Some Natural Bulgarian Silicates.

Orig Pub : Godishnik Khim.-tehnol. in-t, 1955, (1956), 2,
No 1, 113-125.

Abstract : A study of 14 Bulgarian natural silicates (clays,
kaolins, trass and kieselguhr) after thermal act-
ivation in the temperature range from 110 - 400°
and after acid activation with HCl or H₂SO₄ at
a concentration from 1 to 20%. Adsorptive ca-
pacity was checked by the benzene method and
decolorizing power -- by decolorization factor.

Ruschny, D.D. (Nef. Khoz. (Oil Ind., Moscow), Mar. 1957, 64, 65).
Properties of the petroleum are given in detail. It is a heavy, tarry,
aromatic-naphthenic oil containing only 0.32% sulphur and no gasoline
fraction. It has the unusually low freezing point of -24°C. The gas is
dry, with a methane content of over 95%. 150,000 tons of oil were produced
in 1955, and 230,000 tons in 1956, of which half was exported. 50,000 to
60,000 tons are refined in Bulgaria; 120,000 tons will be refined in 1960.
The products are diesel fuels, industrial oils, residual oils, road
bitumens, etc. (L).

Alcoholysis of esters by (mixed) alcoholates and mixed organomagnesium phenolates. D. Ivanov and T. Ruschev. *Ann. univ. Sofia II, Facult. phys.-math.* 29, 331-8 (in French 339-40) (1933).—In the 1st series of reactions between alc. esters of monocarboxylic acids and alcoholates it was found that the heavy radicals R' of alcoholates were displaced by light radicals R_1 of esters. In the reactions between phenolic esters of monocarboxylic acids and alcoholates the aryl radicals R were displaced by alkyls R' . A reverse reaction does not take place. The phenolates were often less sol. in Et_2O than alcoholates. In the 3rd series of reactions between esters of dicarboxylic acids and alcoholates the mixed esters were obtained in 20-8% yield only by displacing the alkyls by other heavier alkyls because 1 part of the motl. r substance is transformed to a sym. ester, corresponding to Mg alcoholate. The mode of operation for the 1st series of expts. is as follows: Prep. 0.15 g.-mol. of Grignard reagent with about 130 cc. Et_2O and oxidise completely at 0° in a closed vessel. Add 0.15 g.-mol. of ester in 50 cc. Et_2O and heat under a reflux for 5 hrs. Hydrolyze the reaction mixt. cautiously at 0° to prevent sapon. Ext. 3 times with Et_2O , wash the ether soln. with 5-10 cc. H_2O , dry over CaCl_2 and distil the ether, using a Vigreux column. Finally distil fractionally. The fraction contg. the ester sought contains also the corresponding alc.; the detn. is performed in EtOH by sapon. The phenolates were prepd. by the reaction of phenols with EtMgBr . These substances were heated for 10 hrs. under a reflux and after hydrolysis the phenol not undergoing reaction was extd. with a freezing mixt. of NaOH .

Design of concrete with portland Portland cement. G. M. FORST (Portland Cement, U.S.S.R., 1954, 181-200).—Forst's formula for the estimation of the strength of a concrete holds for plastic mixes of (A) portland cement concrete as well as for (B) Portland cement concrete. There are variations from the formula for dry or very wet mixes. The rate of strength development of A is < that of B at early ages, but increases later. Thus at 28 days the strength of A is 37-47% of B, whilst at 1 year the difference is only 16-13%. This increase at long ages should be taken into account in design, to avoid uneconomical use of cement. T. W. P.

Title : Fluorescence Spectra of Kerosenes

Orig Pub : An. stiint. Univ. Iasi., 1956, Sec. 1, 2, No 1-2, 199-210

Abstract : Four grades of kerosenes were investigated. In three-minute photography on the E31 Hilger spectrograph there was observed fluorescence in the region of 3200-4600 Å. The glow in the region of the wave lengths longer than 3700 Å, due to the presence of polycyclic compounds (principally anthracene) is observed in kerosenes that were distilled to high temperatures. Kerosene distilled to 272° C practically does not glow in this region. When the kerosenes are diluted in ether, the fluorescence in the region of wavelengths greater than 3700 Å vanishes rapidly. But at the same time there appears and also vanishes a glow in the region $\lambda < 3200$ Å. At greater dilutions, one observes only the fluorescence in the region 3200-3700 Å.

✓ Evaluation of the freeze resistance of concrete by the change of the flexibility modulus. G. M. Rushchuk. *Trudy Vsesoyuz. Inst. po Prochn. i Nauch.-Issledovatel. Rabotam v Tsement. Prom.* 1954, No. 17, 70-88; *Referat. Zhur., Khim.* 1955, Abstr. No. 55835.—For evaluation of the freeze resistance of materials, the use of the modulus of flexural strength is recommended, since the disruption of the material's structure is related to it. The manner of flexural modulus detn. by the resonance frequency of flexure is explained. The theoretical basis of the method, the app. for detn. of the resonance frequency, the method of its detn., and the calcns. of the flexural modulus are given. N. Y.

Title : Methods of Fast Determination of Cement Brand.

Orig Pub: Tr. Gos. Vses. in-t po proektir. i nauch.-issled. rabotam v
tsement. prom-sti, 1956, vyp. 19, 84-114.

Abstract: The experimental data of checking five methods of fast determination of the brand of TsNIPS-1, TsNIPS-2, GNTs, YuzhNII cements and the autoclave method are enumerated. It seems to the authors that the method developed by Giprotsement together with NIITsement (The GNTs method) guarantees a more exact determination of the 28-day activity of cement than the YuzhNII and the autoclave methods. The fast methods of determination of the cement brand

may produce satisfactory results only on condition that the conversion factors of the results of fast tests into the results of standard 28-hour tests are determined for cement of every brand and manufacturing method used in a factory. The statistical method of determination of the cement brand based on the results of 7-day tests and the mean intensity factor R_7/R_28 can be used efficiently by cement factories for the fast determination of the cement brand.

Ruscior, Stefania. La correspondance par plans tangents complètement parallèles entre deux surfaces réglées, dans S_4 . Bul. Inst. Politehn. Iași (N.S.) 3 (1957), 25-28. 1-FW

(Russian and Romanian summaries)

Two planes in a four-dimensional space are called completely parallel [semi-parallel], if their intersection is a line [a point] in the hyperplane at infinity. A correspondence between two ruled surfaces S and S^* , which maps the rectilinear generators of S into those of S^* , is said to be a correspondence by completely parallel tangent planes if the tangent planes at corresponding points are completely parallel. The paper contains a necessary and sufficient condition for the existence of such a correspondence. 2

Geometry.

Fig. 11. The condition of the space with symmetric connection. *UdSSR Math. Zh.* 2, No. 11, 1952.

In a Riemannian space V_n with metric $ds^2 = g_{ij}dx^i dx^j$ ($i, j = 1, \dots, n$), let $P_0(x_0^i)$ be a fixed point and $s(x_0, x)$ be the geodesic arc length between two sufficiently near points $P_0(x_0^i)$ and $P(x^i)$. Then, if the function $\Omega = \int \epsilon s^2$ satisfies $\Delta_2 \Omega = f(\Omega)$, V_n is called centroharmonic with respect to P_0 and if this holds for all base points P_0 , it is called completely harmonic. If the function f happens to be a constant, then the space is called simply centroharmonic or simply harmonic according as the solution $\Delta_2 \Omega = \text{const.}$ holds for one base point or for all base points.

In the paper under review, the author tries to give definitions of simply centroharmonic and harmonic affine spaces of symmetric connection. The author considers a system of paths with affine parameter t passing through a base point $P_0(x_0^i)$ and introduces a vector field by $Y^i = dx^i/dt$. The space is simply centroharmonic with respect to P_0 , if $Y^i_{;i} = n$ and simply harmonic if this solution holds for all base points. The condition for the space to be simply centroharmonic with respect to P_0 is ${}^* \Gamma^i_{ij} y^j = 0$ in a normal coordinate system y^i , from which we obtain an infinite sequence of relations.

(COVER)

In the last section, the author discusses the Riemannian extension V_{2n} :

$$ds^2 = (c_{ij} - 2\Gamma^a_{ij}\xi_a)dx^i dx^j + 2dx^i d\xi_i$$

of an affine space A_n of symmetric connection Γ^i_{jk} , where c_{ij} is a given symmetric covariant tensor in A_n . E. M. Patterson [J. London Math. Soc. 27, 102-107 (1952); these Rev. 13, 986] has shown that, if V_{2n} is simply harmonic, so is A_n and conversely. In this paper, the author obtains a formula for Ω in V_{2n} and uses it to prove a slightly stronger form of Patterson's theorem, namely that, if V_{2n} is harmonic, then it is simply harmonic and so is A_n ; with Patterson's converse that, if A_n is simply harmonic, so is V_{2n} . *K. Yano.*

Chromatographic semimicroanalysis of gases. VIII. Separation and analysis of some halogenated hydrocarbons. Jaroslav Janák and Miroslav Rusek (Ústav pro naftový výzkum, Brno, Czech). Chem. Listy 48, 207-11(1954); cf. C.A. 48, 3854c. The method of chromatographic analysis of gases has been applied to the analyses of halogenated hydrocarbons. R_f values of MeCl, MeBr, EtCl, CH₂:CHCl, and CF₂:CFCl were measured at 20° and 85°: 0.0039, 0.159; 0.0020, 0.120; —, 0.104; 0.0024, 0.110 (at 80°), and 0.0099, 0.214. Analysis at 20° gives better results than at 85°. Absorption of the mixt. of CO₂ and halides in KOH results in partial hydrolysis of the halides increasing in the sequence CF₂:CFCl < CH₂:CHCl < MeCl < EtCl << MeBr. The hydrolysis causes decrease of the measured vol. and makes the measurements less accurate, and the detn. of MeBr impossible. M. Hudlický

RUSEK, M

112. Chromatographic semimicro-analysis of gases. VIII. Separation and analysis of some halogenated hydrocarbons. J. Janák and M. Rusek (*Chem. Listy*, 1951, 48 (2), 207-211).—The chromatographic separation and analysis of mixtures of halogenated hydrocarbons is described. The following R_f values were obtained on silica gel with the passage of the eluting gas (CO_2) at the rate of 0.7 ml per sec.: CH_3Cl , 0.0030; CH_3Br , 0.0020; $CH_2=CHCl$, 0.0024; $CF_2=CFCl$, 0.0009 at 20° C; CH_3Cl , 0.159; CH_3Br , 0.120; C_2H_5Cl , 0.104; $CF_2=CFCl$, 0.214 at 85° C; and $CH_2=CHCl$, 0.110 at 65° to 70° C. In view of the considerable influence of temp. on the adsorption characteristics of this group of gases, better separation is achieved at 20° than at 85° C. Analytical applications of the method are limited owing to partial hydrolysis of the halides during their contact with the KOH in the azotometer, resulting in a decrease of the measured vol. The reactivity increases in the order $CF_2=CFCl < CH_2=CHCl < CH_3Cl < C_2H_5Cl$. The determination of CH_3Br is impossible. G. GLASAR

PhOH and 1 cc. HCl, concg., and distg. H₂O and excess PhOH off under reduced pressure, crystd. from anhyd. AcOH, m. 210-17°. 2,6-Bis(3,5-hydroxymethyl-4-hydroxybenzyl)-*p*-cresol (II) was obtained by dissolving 1 g. I in 8.7 g. 20% NaOH and treating it at room temp. with 2.5 g. 36.5% H₂CO. After 5-7 days the mixt. was neutralized with HCl to pH 7-7.5, then acidified with AcOH to pH 6.5. An oily product crystallized after a few days to give crystals from alc., C₁₆H₁₈O₄, m. 145°. 2,2'-Dihydroxy-5-methylidiphenylmethane (III) was obtained by dissolving 4 g. *o*-hydroxybenzyl alc. in 30 g. melted *p*-cresol and 2 ml. concd. HCl, boiling distg. excess *p*-cresol off with steam, and emulsifying remainder with H₂O. After a few days III crystallized from alc. and m. 99-101°. sol. in C₆H₆. 2,4'-Dihydroxy-5-methylidiphenylmethane (IV) was obtained by condensing *p*-hydroxybenzyl alc. with *p*-cresol. Crystn. begins from emulsion to give crystals from C₆H₆, m. 133-40°. 2,6-Bis[5-(4-hydroxybenzyl)-2-hydroxybenzyl]-*p*-cresol (V), obtained by dissolving 6 g. 4,4'-dihydroxydiphenylmethane in 60 ml. concd. AcOH. At 40°, 3 g. 2,6-dimethylol-*p*-cresol was added with stirring, heated, and treated with 2 ml. concd. HCl, then brought to boiling, and poured into 1 l. H₂O. The white ppt. is washed and dissolved in hot xylene. V is a white noncryst. substance, C₂₄H₂₈O₆, softening above 110°. 2,4,6-Tris(3-methyl-5-hydroxybenzyl)phenol (VI) was obtained by dissolving 2 g. Na 2,4,6-trimethylolphenate in 50 g. melted *p*-cresol. The mass is heated, then 10 ml. concd. HCl slowly added, heating continued (water bath) for 15-20 min., the pptd. NaCl filtered, and excess *p*-cresol distd. off with steam. C₂₁H₂₄O₄, crystals from C₆H₆, m. 182,5-4°. 3,3',5,5'-Tetrakis(2-hydroxy-5-methylbenzyl)-4,4'-dihydroxydiphenylmethane (VII) was obtained by dissolving 2.3 g. 3,3',5,5'-tetramethylol-4,4'-dihydroxydiphenylmethane in 20 g. melted *p*-cresol, adding at 35° 1 ml. concd. HCl (temp. rises to 60°), distg. excess *p*-cresol off with steam, and crystg. a few times from xylene in gellike form, then from toluene and benzene, m. 201-2°, sol. in Et₂O, MeOH, EtOH, and acetone.

304. Chromatographic semi-micro analysis of gases. IX. Determination of nitrous oxide. I. Janák and M. Kocok (Chem. Listy, 1964, 48 [3], 307-309). ~~Chromatographic~~ chromatographic technique of gas analysis is suitable for the rapid estimation of N_2O in admixture with hydrogen, nitrogen, methane and ethane, in commercial N_2O and in natural gas. The R_f values of N_2O , measured in the usual way in an adsorption column 220 mm long and 5-1 mm in diameter with the eluting gas (CO_2) passing at the rate of 0.7 ml per sec., were as follows: on activated carbon, 0.0264 at 20° C and 0.234 at 80° C; and on silica gel, 0.0428 at 20° C and 0.297 at 80° C. Owing to the slight solubility of N_2O in conc. KOH, the nitrometer should be filled with a KOH soln. that has been exposed to an atmosphere containing N_2O . (C. GLASER)

 gaseous hydrocarbons. M. Kurek and A.
 Lazarus (Inst. Petrol. Res. Univ. Czechoslovakia).
 Coll. Czech Chem Commun. 1953 20(6): 1192-1205 --
 (14) The separation of next homologous cyclo-
 propanes, e.g., cyclopropane and methylenecycloprop-
 ane, and cyclopropane and cyclobutane, on silica gel
 and charcoal at 20° C and 80° C is described. The
 sorption on silica gel increases with the increasing
 energy content, i.e., strain, for hydrocarbon mole-
 cules having the same number of carbon atoms and
 does not depend on the boiling point. The order of
 elution of mixtures of gases containing either 2 or
 3 carbon atoms is, e.g., ethane, ethylene, acetylene
 and propane, cyclopropane, propylene, propyne.
 The quantitative analysis of a mixture of air,
 CO, ethane, ethylene, propylene and cyclobutane
 with an error of 0-4 per cent. and of anaesthetic
 mixtures of air, He, O, N₂O, ethylene and cyclo-
 propane with an error of 1 per cent. is possible.

Title : Classification of Czechoslovak Natural Gases.

Orig Pub: Paliva, 1956, 36, No 10, 327-329

Abstract: Generalized data are presented concerning the
genesis, chemical composition and calorific value
of Czechoslovak natural gases, and on the basis
of these data a classification of these gases is
evolved, whereby they are subdivided into three
types according to chemical indices and into four
types according to genesis indices.

TITLE: Apparatus Using Flame-Ionization Detection

PERIODICAL: Chemické listy, 1960, Vol.54, No.11, pp.1173-1182 + 1 plate

TEXT: Factors controlling the design of a Czechoslovak high-temperature gas chromatography apparatus using a flame ionization detector are discussed and operating data are given. A diagrammatic lay-out of the apparatus and of the electrical circuit in the detector are shown. A photograph of the complete and mass-produced instrument is included. Its design follows conventional lines: The apparatus is housed in a thermostat suitable for a temperature range up to 350°C and capable of employing four columns, each of them U-shaped and approximately 850 mm in length. Thermostating is achieved by hot air which is made to circulate by means of a fan. The design of the flame ionization detector differs from that introduced originally to gas chromatography by I.G.McWilliam (Gas Chromatography, ed. D.H.Desty, Butterworth Scientific Publications, London, 1958, p.142). In the McWilliam model the issuing gas is being burnt at a jet made from a hypodermic needle which, at the same time, serves as the positive pole for Card 1/5

the flame conductance measurements. The negative pole consists of a piece of 30 mesh brass gauze about 1 cm above the needle. In the Czechoslovak design the jet is a steel capillary of 0.5 mm bore above which are placed two platinum wire electrodes on top of each other and perpendicular to the axis of the flame. In series with the electrodes is a battery of 120 to 200 V and a resistor, across which a recorder is connected. The following operating data were investigated: a) Time factor for the establishing and maintenance of constant temperature parameters. b) Maintenance of constant pressure conditions at varying flow-rates of carrier gases. After the introduction of mercury manostats, the deviations of pressure at flow-rate changes of 100% amounted to no more than 1.5%. c) Effect of voltage on signal sensitivity at constant weight of chromatographed compounds. Results are summarized in a table indicating voltages required for complete ionization at different flow rates and varying distances of electrodes. d) Effect of variations of N₂ and H₂-flow on signal sensitivity and stability of base line. Sensitivity is more affected by change in N₂-flow rate than that of H₂.

The effect of N_2 -flow, on other hand, on the stability of the base line is negligible, while that of H_2 is considerable.

e) Effect of electrode distance and of their shape. Sensitivity decreases as the distance between the electrodes increases and a linear relationship is shown to exist. Position and shape of upper electrode is not of great importance, but detector can function properly only on condition that the lower electrode is placed within the ionized space. The optimum distance of the lower electrode from the tip of the jet is determined by the maximum concentrations of the eluted fractions passing through the detector. Flame profiles and temperature contours are studied in this connection. Ionization gradients leading to inversions of chromatograms and measures for their elimination are discussed. Inversions are more likely to occur at low flow-rates.

f) The performance of the instrument as a tool of analytical chemistry is discussed and results of analyses of different mixtures are given. A special study is devoted to partition chromatography homologues. It is considered that the concentration of ions per mole in a series of homologous

hydrocarbons increases in proportion to the number of carbon atoms in the molecule. The conductivity of the flame is explained by the formation of carbon ions, which are considered a transitory stage before the combustion of the hydrocarbons to carbon dioxide. In compounds, therefore, in which the carbon atoms may already be in an oxidation stage, a transition to carbon ions is not possible and these compounds will show characteristics associated with compounds having a lower number of carbon atoms, e.g. acetone will behave like a compound containing only two carbon atoms. Compounds which do not contain carbon will show similar characteristics. The method has been found also very suitable for the analyses of biological mixtures and for medicinal work (acetone assay in diabetic urine etc). Other examples include results of analyses of coal tar constituents. Column packings, temperatures and other details are tabulated for each particular type of analyses. Illustrations that are included show the general arrangement of apparatus, a schematic diagram of the electrical circuit of the detector and a photograph of the complete instrument. There are
